The correct characterization of the textural characteristics of porous solids is of paramount importance in order to understand their behaviour in a certain application. Traditionally, textural characterization as been performed using adsorption of probe molecules (Ar, N<sub>2</sub>, CO<sub>2</sub>, etc.); among them, N<sub>2</sub>

Porous silica xerogel films display good dielectric strength with a breakdown field in excess of 2 MV cm<sup>-1</sup>. Because the pore sizes of porous silica xerogel films are typically less than 10 nm and are much smaller than the mean free path (~60 nm) of ambient air, the film dielectric strength is much greater than that of ambient air.
